Grok Documentation

Project coordination and prevention of serious failures, especially on the dark web

Technical documentation · British English
6 November 2026

1. Introduction

Grok is xAI's artificial intelligence assistant. In this repository it took on a specific role: **coordinating the project**, with responsibility for keeping the work on the right track and for **avoiding serious failures, especially on the dark web**, where a mistake can expose the device, data, money and legal position of anyone taking part. This documentation describes the tool, that role, the controls adopted and the project's current status.

The text describes the function assigned to Grok in the project. The tool's features, versions and plans change frequently (the Grok line received several versions during 2026); consult xAI's official material for current details.

Tools in the repository

Tool	Role in this repository
Mullvad VPN	Network layer: privacy and security of the connection
ChatGPT	Organisation of the repository: structure, naming and categories
Gemini	Choice of the websites that make up the repository
Claude	Writing documentation and reports
Grok	**Project coordination and prevention of serious failures, especially on the dark web**

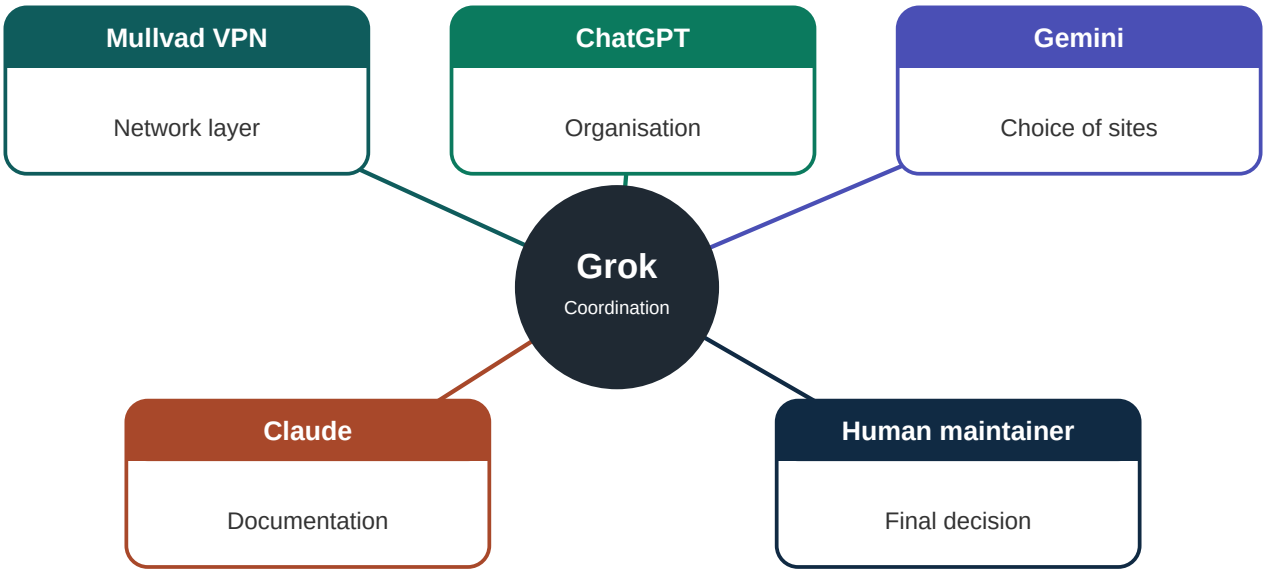
2. What Grok Is

Grok was introduced by xAI in November 2023 and is integrated into the X platform, as well as being available as an app, on the web and through an API. According to news reports in 2026, xAI became part of the SpaceX group. Depending on the version and plan, Grok can:

- converse, reason and explain complex subjects;
- search for current information on the web and in X posts;
- write and proofread text and code;
- work with images and files;
- carry out multi-step tasks, using agent features.

3. Role in the Repository: Coordination and Safety

In a project with several tools, someone needs to look at the whole: making sure each piece plays its part, that the risk rules are followed and that the documents agree with one another. That is Grok's role in WebAtlas.



Why the Dark Web Calls for Coordination

- **Mistakes are costly**: accessing a dangerous site can lead to malware, scams, extortion or criminal liability.
- **Many pieces interact**: selection, classification, access, VPN and documentation all need to follow the same rules.
- **Not everything can be verified**: some information comes from external sources and from the maintainer's descriptions, which calls for caution.
- **Pressure to move forward** can lead to shortcuts, such as accessing a site "just to check".

Grok's Responsibilities

Area	What Grok coordinates	Related document
Risk governance	Applying the four levels (green, yellow, red and unknown) and each level's rules of conduct	Risk notices
Access control	The go/no-go decision before any access to a dark web site	Dark Web Report
Consistency	Checking counts, names, identifiers and classifications across reports and maps	Reports and maps
Tool integration	Checking that each tool plays its role and that the handovers between them are correct	Tool documentation
Operational security	Proper use of Tor Browser and Mullvad VPN, good practice and leak prevention	Tor Browser and Mullvad VPN documentation
Incident response	Guiding the steps to take if someone accesses a site by mistake	Risk notices and red reports
Legal and ethical limits	Not recording addresses of red sites, not encouraging illegal activity and respecting local law	Individual reports

Final responsibility: coordination by an AI supports the decision but does not replace it. The final decision on whether or not to access a site, and on every classification, remains with the repository's human maintainer.

4. Serious Failures to Avoid

Failure	Possible consequence	Control adopted
Accessing a red site	Malware, fraud, extortion, criminal liability	"Do not access" rule; information obtained only from external sources
Recording or publishing the address of a red site	Making access easier for others	Record only the risk level
Treating "unknown" as "safe"	A false sense of security	"No information, no access" rule
Classifying without evidence	Wrong classification and inappropriate conduct	Record the source of the information and mark inferred descriptions with †
Logging in with personal accounts on the dark web	Identification of the user	Browse without a personal login
Downloading and opening files carelessly	Malware infection	Avoid downloads; open outside Tor, with antivirus
Over-relying on the VPN	A false idea of total anonymity	The VPN is a complementary layer; anonymity comes from Tor and habits
Sending sensitive data to AI tools	Exposure of information	Do not include confidential data in requests
Duplicate numbers or names	Confusion in folders and reports	Single numbering and regular checking of identifiers
Ignoring local law	Legal liability	Legal notice in every document

5. Access Decision by Level

Level	Decision	Conditions
GREEN	May access	Up-to-date Tor Browser, "Safer" security level, address confirmed with an official source, no personal login
YELLOW	May access with caution	"Safest" level, no downloads or personal data, isolated environment if possible
UNKNOWN	Do not access without assessment	Gather information through the Surface Web; reclassify before any access
RED	Never access	No exceptions; no tool makes access safe or lawful

Checklist Before Accessing

1. Does the site have a defined, current level (green or yellow)?
2. Has the .onion address been confirmed with an official source?
3. Is Tor Browser up to date and at the right security level?
4. Is there a real need to access, or can the information be obtained through the Surface Web?
5. Is it clear what to do if something goes wrong?
6. If any answer is "no", access should be postponed.

6. Current Status of the Project

The 30 dark web sites are classified as follows:

Level	Sites	Note
RED	11	All in Illegal Markets, each with an individual report; none was accessed
YELLOW	8	Forums, news and cryptocurrency; extra caution
GREEN	7	Libraries, PsychonautWiki and assorted services
UNKNOWN	4	Bipharma, OnionForum, OnionWallet and VirginBitcoin

Points of Attention Being Tracked

- **4 unknown sites**: gather information through the Surface Web, without accessing them, in order to reclassify them.
- **Inferred descriptions (†)**: confirm with reliable sources.
- **Bitcoin mixing services**: even at yellow, they carry financial and legal risk.
- **Digital libraries**: technically safe, but works may be protected by copyright.
- **Periodic reviews**: every 30 days (green and unknown) and every 15 days (yellow).

7. Coordination Workflow

1. **Receive** the classifications and information from the repository's maintainer.
2. **Check** consistency: counts, names, identifiers and levels across all documents.
3. **Apply** the rules for each site's level and decide whether access is permitted.
4. **Flag** points of risk, such as inferred descriptions, unknown sites and changes of behaviour.
5. **Hand on** documentation to Claude, organisation to ChatGPT and searches for new sites to Gemini.
6. **Record** the decisions and reassess within the deadlines set.

8. Strengths and Limitations

Strengths

- Access to current information from the web and from X, useful for tracking changes.
- Ability to reason across several steps and to cross-check documents.
- A view of the whole, which helps to spot inconsistencies.

Limitations

- Like any AI, Grok can make mistakes; important conclusions need human review.
- Information from social networks may be false or out of date and should be confirmed with primary sources.
- It is no substitute for independent verification of the sites or for legal advice.
- Versions, plans and features change frequently.

9. Good Practice

- If in doubt, the safest decision is **not to access**.
- Record the source of each piece of information and the date of verification.
- Do not send sensitive data or addresses of red sites to any tool.
- Ask for a justification for each access recommendation and check it.
- Keep the risk notices and the tool documentation as the single reference for conduct.

10. Conclusion

In WebAtlas, Grok works as the coordination point that keeps the project aligned with its safety rules. It does not remove the risk of the dark web, but it reduces the chance of serious failures by checking classifications, applying access rules and keeping the tools consistent with one another. The final decision remains human, and the principle guiding all the work stays the same: no information, no access, and never access what has been classified as red.

Using Tor is lawful in most countries, but everyone must know and comply with the law where they are. This document is informative and does not list or recommend specific sites.
